**Keywords:** Brillouin scattering, phonon spectrometer, photonics, femtowatt, pump-probe, instrument, room-temperature, nano-acousto-optic devices

Brillouin scattering is the inelastic scattering of light from acoustic phonons. Spontaneous Brillouin scattering is light scattering specifically with the thermodynamic fluctuations in a material. Sufficient optical power elevates this spontaneous process into stimulated Brillouin scattering: a regime in which the optical fields augment the optical properties of the material, greatly enhancing the optomechanical response. This occurs as the backscattered (e.g. Stokes) light beats with the incident pump light to induce an electrostrictive modulation that reinforces the acoustic phonons in the material. It would be desirable to introduce a high-powered fourth optical field dedicated to electrostrictive reinforcement, further stimulating the acoustic field, however phase matching conditions require that its frequency and wavevector be identical to that of the backscattered light, preventing distinguishability.

In this work, we present a coherently stimulated Brillouin spectrometer that utilizes a detuned pump-probe design to perform traveling-wave phonon spectroscopy at scales previously unachievable with traditional stimulated Brillouin techniques. With this method, we achieve sub-10 femtowatt sensitivity and enable room temperature traveling-wave phonon spectroscopy at the micrometer scale. We demonstrate the capabilities of the instrument by observing Brillouin scattering at room temperature in 1 centimeter of UHNA3 fiber and 100 micrometers of bulk carbon disulfide liquid. This instrument opens the door to nanometer-scale Brillouin spectroscopy with usage of higher optical powers and enables the characterization and development of novel nano-acousto-optic devices.

### Instrument design

The design of the instrument is shown in the schematic in Fig. 1. A pump and Stokes signal is synthesized from a single tunable laser source for coherent stimulation of the sample. The pump signal ( $\omega_{Pump}$ ) is amplified by an erbium-doped fiber amplifier (EDFA) and passed through a variable optical attenuator (VOA) for power control. The output is then polarization-controlled to reflect at a polarizing beam splitter (PBS) for injection into the sample. For Stokes synthesis, an AC signal ( $\Omega$ ) is supplied to an intensity modulator with carrier frequency nulled and a tunable filter is used to select one side band output ( $\omega_{Pump} - \Omega$ ). This Stokes light is then amplified by an EDFA, passed through a VOA, and polarization-controlled to reflect at a second PBS for counter-propagation to the pump through the sample.

A separate tunable laser ( $\omega_{Probe} = \omega_{Pump} + \Delta k$ ) is used to synthesize the probe and local oscillator (LO). Probe light is amplified by an EDFA and fed through a VOA. A polarization controller aligns the polarization axis of the probe light for transmission through the first PBS and copropagation with the pump into the sample. Backscattered probe light exits the sample and transmits back through the first PBS, whereas the

orthogonally polarized Stokes light reflects at this same point to be diverted to a tap for power monitoring. The backscattered signal ( $\omega_{Signal} = \omega_{Probe} + \Omega$ ) then routes through two subsequent circulators for spectral filtering by a 5 GHz bandpass tunable filter. This filter allows the frequency-shifted probe light to pass while rejecting (1) any reflected probe light, and (2) any reflected, transmitted, or backscattered pump or Stokes light that was not already diverted by the PBS.

The filtered signal heterodynes via a 99-1 splitter with the LO ( $\omega_{LO} = \omega_{Probe} + 2\pi \times 40MHz$ ), which has been frequency-upshifted by an acousto-optic modulator (AOM) and controlled to be copolarized with the backscattered signal. We consider only the subtracted frequency term of the heterodyne process as all others (original, additive, higher-harmonic, and more complicated intermodulation product frequency terms) are well beyond the range of detection. This heterodyned signal ( $\omega_{signal} = \Omega + 2\pi \times 40MHz$ ) is then captured by a photodiode detector and heterodyned again by a radio frequency (RF) mixer with a second AC signal ( $\Omega - 2\pi \times 5MHz$ ) that synchronously sweeps with the Stokes-synthesis AC signal. The resulting constant signal ( $\omega_{Lock-in} = 2\pi \times 45MHz$ ) is passed through a 50 MHz low-pass filter, amplified with an RF amplifier, and finally supplied to a lock-in amplifier for data collection. The lock-in amplifier is able to lock-in on the constant input frequency throughout a measurement as both AC signals, one supplied to the RF mixer and the other for Stokes synthesis, are synchronously swept through a range of frequencies to take a measurement.

## Measurements

We consider two example targets to demonstrate the capabilities of the instrument, one fiber-coupled and one bulk material. Fig. 2 shows the spectra captured for 1 cm of UHNA3 fiber. The spectral shape is that of the expected lorentzian function, with the peak ([9.18 GHz]) indicating the Brillouin resonance frequency and the FWHM ([80 MHz]) indicating the dissipation rate of the fiber. [comparison to regular SBS for some measurable length of UHNA3?]

Fig. shows the spectral measurements achieved by the instrument, overlaid with finite-difference simulation data. In Fig. we see the expected lorentzian spectral shape in good alignment with simulation data for guided longitudinal modes in the core of the UHNA3 fiber. In Fig. , however, we see a distortion of this lorentzian shape. This is expected for partially unguided longitudinal modes, such as is the case for a bulk liquid filling the volume of a ...

Fig. 2 shows a measurement of 1cm of UHNA3 fiber.

First, we measured Brillouin scattering in a 1-centimeter-long UHNA3 fiber at room temperature and with sub-Watt optical power (Fig. ). Figure , clearly displays the Brillouin scattering features with remarkable signal-to-noise ratio, highlighting the effectiveness of our apparatus in isolating the backscattered probe light. This observation serves as one of the main showcases of the instrument's capability.

Fig. 2 1cm UHNA3 (fit?)

Fig. 3 100um CS2

Next, we performed Brillouin scattering measurements on a 4-millimeter-thick bulk carbon disulfide sample in a free-space optics arrangement. The observed spectrum, presented in Figure 2, exhibits well-resolved Brillouin scattering peaks. This successful measurement in a bulk sample demonstrates the versatility and adaptability of our instrument to various experimental configurations, further emphasizing the instrument's capability.

Lastly, we conducted a measurement in a 1-millimeter-long UHNA3 fiber under low-power conditions, with only 10 microwatts of power at the sample. Despite the reduced sample length and low power, the instrument's sensitivity allowed us to observe distinct Brillouin scattering features in the spectrum, as illustrated in Figure 3. This result underscores the potential of our spectrometer for nanoscale measurements and

### 1 cm UHNA3 Phase-Matching Bandwidth

**Fig. 4** Phase-matching sinc func

serves as a demonstration of the instrument’s sensitivity, defining the sensitivity floor of the apparatus.

These three observations collectively showcase the high sensitivity, broad applicability, and impressive capabilities of our coherent stimulated phonon spectrometer in measuring Brillouin scattering across different sample types, scales, and power levels.

## Appendix A Phase Matching

### A.1 Relaxation of Phase Matching Conditions

### A.2 Phase Matching Bandwidth Experiments

### A.3 Theoretical Comparison of Phase Matching Bandwidth

## Appendix B Coupled-Wave Equations

Here we derive the coupled wave equations that describe coherent stimulated Brillouin scattering involving a pump, Stokes, probe, and backscattered optical field given respectively by

$$\tilde{E}_P(z, t) = A_P e^{i(k_P z - \omega_P t)} + c.c. \quad (B1)$$

$$\tilde{E}_S(z, t) = A_S e^{i(k_S z - \omega_S t)} + c.c. \quad (B2)$$

$$\tilde{E}_{Pr}(z, t) = A_{Pr} e^{i(k_{Pr} z - \omega_{Pr} t)} + c.c. \quad (B3)$$

$$\tilde{E}_{Sig}(z, t) = A_{Sig} e^{i(k_{Sig} z - \omega_{Sig} t)} + c.c. \quad (B4)$$

and a common acoustic field given by

$$\tilde{\rho}(z, t) = \rho_0 + \rho(z, t) e^{i(qz - \Omega t)} + c.c., \quad (B5)$$

where  $\Omega = \omega_P - \omega_S$  and  $q = k_P - k_S = 2k_P$ .

### B.1 Acoustic Field

We start by assuming that the material obeys the acoustic wave equation,

$$\frac{\partial^2 \tilde{\rho}}{\partial t^2} - \Gamma' \nabla^2 \frac{\partial \tilde{\rho}}{\partial t} - v^2 \nabla^2 \tilde{\rho} = \nabla \cdot \vec{f}, \quad (B6)$$

where  $v$  is the sound speed in the material and  $\Gamma'$  is a damping parameter given by

$$\Gamma' = \frac{1}{\rho} \left[ \frac{4}{3} \eta_s + \eta_b + \frac{\kappa}{C_p} (\gamma - 1) \right], \quad (B7)$$

where  $\eta_s$  and  $\eta_b$  are the shear and bulk viscosity coefficients of the material, respectively. The source term on the right side of Eq. (B6) is the divergence of the electrostrictive force:

$$\vec{f} = \nabla p_{st} = \nabla \cdot \left[ -\frac{1}{2} \epsilon_0 \gamma_e \left( \langle \tilde{E}_P \cdot \tilde{E}_S \rangle + \langle \tilde{E}_{Pr} \cdot \tilde{E}_{Sig} \rangle \right) \right], \quad (B8)$$

which yields, after applying the slowly varying amplitude approximation,

$$\nabla \cdot \vec{f} = \epsilon_0 \gamma_e q^2 (A_P A_S^* + A_{Pr} A_{Sig}^* e^{i\Delta k z}), \quad (B9)$$

Where  $\Delta k = (k_{Pr} - k_{Sig}) - (k_P - k_S)$  is the phase mismatch between the four optical fields. Only two electrostrictive terms survive terms after accounting for the orthogonal polarization of the pump and Stokes fields with respect to that of the probe and backscattered signal. Inserting this electrostrictive force term and the acoustic field (Eq. (B5)) into Eq. (B6) and assuming a slowly varying acoustic amplitude we find

$$-2i\Omega \frac{\partial \rho}{\partial t} - \Gamma' 2iq^2 \Omega \rho - 2iqv^2 \frac{\partial \rho}{\partial z} = \epsilon_0 \gamma_e q^2 (A_P A_S^* + A_{Pr} A_{Sig}^* e^{i\Delta k z}), \quad (B10)$$

which can be restated in terms of the Brillouin linewidth,  $\Gamma_B = q^2\Gamma'$ , as

$$-2i\Omega \frac{\partial \rho}{\partial t} - 2i\Omega \Gamma_B \rho - 2iqv^2 \frac{\partial \rho}{\partial z} = \epsilon_0 \gamma_e q^2 (A_P A_S^* + A_{Pr} A_{Sig}^* e^{i\Delta k z}). \quad (B11)$$

Given the phonon dispersion relations  $\Omega_B = |q_B|v$  and  $\Omega^2 = q^2 (v^2 - i\Omega\Gamma')$ , Eq. (B11) can be rewritten as

$$-2i\Omega \frac{\partial \rho}{\partial t} + (\Omega^2 - \Omega^2 - i\Omega\Gamma_B) \rho - 2iqv^2 \frac{\partial \rho}{\partial z} = \epsilon_0 \gamma_e q^2 (A_P A_S^* + A_{Pr} A_{Sig}^* e^{i\Delta k z}). \quad (B12)$$

We take the common assumption that the phonon propagation distance is small compared to the distance over which the source term varies significantly, which allows the spatial derivative term in Eq. (B12). We further assume steady-state conditions such that the time derivative term also vanishes, leaving

$$(\Omega_B^2 - \Omega^2 - i\Omega\Gamma_B) \rho = \epsilon_0 \gamma_e q^2 (A_P A_S^* + A_{Pr} A_{Sig}^* e^{i\Delta k z}). \quad (B13)$$

We thus find the acoustic field amplitude to be

$$\rho(z, t) = \epsilon_0 \gamma_e q^2 \frac{A_P A_S^* + A_{Pr} A_{Sig}^* e^{i\Delta k z}}{\Omega_B^2 - \Omega^2 - i\Omega\Gamma_B}. \quad (B14)$$

## B.2 Optical Fields

We now turn to the spatial evolution of the optical fields, described by the wave equation,

$$\frac{\partial^2 \tilde{E}_i}{\partial z^2} - \frac{n^2}{c^2} \frac{\partial^2 \tilde{E}_i}{\partial t^2} = \frac{1}{\epsilon_0 c^2} \frac{\partial^2 \tilde{P}_i}{\partial t^2}, \quad (B15)$$

where  $i$  denotes the four optical fields, namely: pump, Stokes, probe, and backscattered signal. The total nonlinear polarization that gives rise to the source term in the wave equation is given by

$$\tilde{P} = \epsilon_0 \Delta \chi \tilde{E} = \epsilon_0 \Delta \epsilon \tilde{E} = \epsilon_0 \rho^{-1} \gamma_e \tilde{\rho} \tilde{E}. \quad (B16)$$

The parts of  $\tilde{P}$  that can act as phase-matched source terms for the optical fields are

$$\tilde{P}_P = p_P e^{i(k_P z - \omega_P t)} + c.c. = \frac{1}{2} \epsilon_0 \rho_0^{-1} \gamma_e \rho A_S e^{i(k_P z - \omega_P t)} \quad (B17)$$

$$\tilde{P}_S = p_S e^{i(-k_S z - \omega_S t)} + c.c. = \frac{1}{2} \epsilon_0 \rho_0^{-1} \gamma_e \rho^* A_P e^{i(-k_S z - \omega_S t)} \quad (B18)$$

$$\tilde{P}_{Pr} = p_{Pr} e^{i(k_{Pr} z - \omega_{Pr} t)} + c.c. = \frac{1}{2} \epsilon_0 \rho_0^{-1} \gamma_e \rho A_{Sig} e^{i(k_{Pr} z - \omega_{Pr} t)} e^{i\Delta k z} \quad (B19)$$

$$\tilde{P}_{Sig} = p_{Sig} e^{i(-k_{Sig} z - \omega_{Sig} t)} + c.c. = \frac{1}{2} \epsilon_0 \rho_0^{-1} \gamma_e \rho^* A_{Pr} e^{i(-k_{Sig} z - \omega_{Sig} t)} e^{-i\Delta k z}. \quad (B20)$$

Inserting the optical fields (Eqs. B1-B4) and phase-matched source terms (Eqs. B17-B20) into Eq. (B15), we obtain

$$\frac{\partial A_P}{\partial z} + \frac{n}{c} \frac{\partial A_P}{\partial t} = \frac{i\omega_P \gamma_e}{2nc\rho_0} \rho A_2 \quad (B21)$$

$$-\frac{\partial A_S}{\partial z} + \frac{n}{c} \frac{\partial A_S}{\partial t} = \frac{i\omega_S \gamma_e}{2nc\rho_0} \rho^* A_P \quad (B22)$$

$$\frac{\partial A_{Pr}}{\partial z} + \frac{n}{c} \frac{\partial A_{Pr}}{\partial t} = \frac{i\omega_{Pr} \gamma_e}{2nc\rho_0} \rho A_{Sig} \quad (B23)$$

$$-\frac{\partial A_{Sig}}{\partial z} + \frac{n}{c} \frac{\partial A_{Sig}}{\partial t} = \frac{i\omega_{Sig} \gamma_e}{2nc\rho_0} \rho^* A_{Pr} \quad (B24)$$

We again assume steady-state conditions, allowing the time derivative term to be dropped. Plugging in the acoustic field amplitude (Eq. B14), we arrive at the coupled-amplitude wave equations for the optical fields,

$$\frac{\partial A_P}{\partial z} = \frac{i\epsilon_0\omega_P q^2 \gamma_e^2}{2nc\rho_0} \frac{A_P |A_S|^2 + A_{Pr} A_{Sig}^* A_S e^{i\Delta k z}}{\Omega_B^2 - \Omega^2 - i\Omega\Gamma_B} \quad (\text{B25})$$

$$\frac{\partial A_S}{\partial z} = -\frac{i\epsilon_0\omega_S q^2 \gamma_e^2}{2nc\rho_0} \frac{|A_P|^2 A_S^* + A_{Pr} A_{Sig}^* A_P e^{-i\Delta k z}}{\Omega_B^2 - \Omega^2 - i\Omega\Gamma_B} \quad (\text{B26})$$

$$\frac{\partial A_{Pr}}{\partial z} = \frac{i\epsilon_0\omega_{Pr} q^2 \gamma_e^2}{2nc\rho_0} \frac{A_P A_S^* A_{Sig} + A_{Pr} |A_{Sig}|^2 e^{i\Delta k z}}{\Omega_B^2 - \Omega^2 - i\Omega\Gamma_B} \quad (\text{B27})$$

$$\frac{\partial A_{Sig}}{\partial z} = -\frac{i\epsilon_0\omega_S q^2 \gamma_e^2}{2nc\rho_0} \frac{A_P A_S^* A_{Pr} + |A_{Pr}|^2 A_{Sig}^* e^{-i\Delta k z}}{\Omega_B^2 - \Omega^2 - i\Omega\Gamma_B} \quad (\text{B28})$$

Integrating Eq. B28 along the effective length gives the amplitudes of each optical field,

$$A_P = \frac{i\epsilon_0\omega q^2 \gamma_e^2}{2nc\rho_0} \frac{A_P |A_S|^2 + A_{Pr} A_{Sig}^* A_S}{\Omega_B^2 - \Omega^2 - i\Omega\Gamma_B} \frac{e^{i\Delta k L} - 1}{i\Delta k}, \quad (\text{B29})$$

$$A_S = -\frac{i\epsilon_0\omega q^2 \gamma_e^2}{2nc\rho_0} \frac{|A_P|^2 A_S^* + A_{Pr} A_{Sig}^* A_P}{\Omega_B^2 - \Omega^2 - i\Omega\Gamma_B} \frac{e^{-i\Delta k L} - 1}{-i\Delta k}, \quad (\text{B30})$$

$$A_{Pr} = -\frac{i\epsilon_0\omega q^2 \gamma_e^2}{2nc\rho_0} \frac{A_P A_S^* A_{Sig} + A_{Pr} |A_{Sig}|^2}{\Omega_B^2 - \Omega^2 - i\Omega\Gamma_B} \frac{e^{i\Delta k L} - 1}{i\Delta k}, \quad (\text{B31})$$

$$A_{Sig} = -\frac{i\epsilon_0\omega q^2 \gamma_e^2}{2nc\rho_0} \frac{A_P A_S^* A_{Pr} + |A_{Pr}|^2 A_{Sig}^*}{\Omega_B^2 - \Omega^2 - i\Omega\Gamma_B} \frac{e^{-i\Delta k L} - 1}{-i\Delta k}. \quad (\text{B32})$$

The intensity of the backscattered signal is given by the magnitude of the time-averaged Poynting vector, given by

$$I_i = 2n_i\epsilon_0 c |A_i|^2, \quad i = 1, 2, 3, \quad (\text{B33})$$

which gives

$$I_{Sig} = \frac{\epsilon_0^2 \omega^2 q^4 \gamma_e^4}{4n^2 c^2 \rho_0^2} \frac{|A_P|^2 |A_S|^2 |A_{Pr}|^2}{(\Omega_B - \Omega)^4 - \Omega^2 \Gamma_B^2} \left| \frac{e^{-i\Delta k L} - 1}{-i\Delta k} \right|^2. \quad (\text{B34})$$

The squared modulus term containing  $\Delta k$  can be reduced as

$$\begin{aligned} \left| \frac{e^{-i\Delta k L} - 1}{-i\Delta k} \right|^2 &= \frac{(e^{-i\Delta k L} - 1)(e^{i\Delta k L} - 1)}{(\Delta k)^2} = \frac{L^2}{(\Delta k L)^2} \left[ 2 - 2 \left( \frac{e^{i\Delta k L} + e^{-i\Delta k L}}{2} \right) \right] \\ &= \frac{2L^2(1 - \cos \Delta k L)}{(\Delta k L)^2} = \frac{4L^2 \sin^2(\frac{\Delta k L}{2})}{(\Delta k L)^2} = \frac{L^2 \sin^2(\frac{\Delta k L}{2})}{(\frac{\Delta k L}{2})^2} = L^2 \text{sinc}^2\left(\frac{\Delta k L}{2}\right) \end{aligned} \quad (\text{B35})$$

and the optical fields can be written in terms of the intensities

$$I_{Sig} = \frac{\epsilon_0^2 \omega^2 q^4 \gamma_e^4}{4n^2 c^2 \rho_0^2} \frac{I_P I_S I_{Pr}}{(\Omega_B - \Omega)^4 - \Omega^2 \Gamma_B^2} L^2 \text{sinc}^2\left(\frac{\Delta k L}{2}\right). \quad (\text{B36})$$

Here we have taken the real part and dropped the very small terms containing the signal amplitude. Defining the intensities as  $I_i = 2n_i\epsilon_0 c A_i A_i^*$ , the backscattered signal intensity is reduced to [see green writing to far right in onenote coupled wave equations of CABS]

To find the power of the backscattered signal, we would integrate this intensity over the effective area. Approximated for fiber as  $\pi r^2$  where  $r$  is the effective mode field diameter, this becomes

$$P_{Sig} = \pi r^2 \frac{\epsilon_0^2 \omega^2 q^4 \gamma_e^4}{4n^2 c^2 \rho_0^2} \frac{P_P P_S P_{Pr}}{(\Omega_B - \Omega)^4 - \Omega^2 \Gamma_B^2} L^2 \text{sinc}^2 \left( \frac{\Delta k L}{2} \right). \quad (\text{B37})$$

## Appendix C Instrument Details

### C.1 List of Salient Components

### C.2 Laser Output: Whisper Mode vs. Dither Mode

### C.3 Lock-in Settings

## Appendix D Experimental Techniques

### D.1 Background Subtraction: Probe Off, Sample In

### D.2 Background Subtraction: Probe On, Sample Out

### D.3 Polarization Control Limit

### D.4 Pump, Stokes, Probe Polarization Optimization

### D.5 Local Oscillator Polarization Optimization

### D.6 Lock-in Detector Settings

### D.7 Detection Bandwidth

## Appendix E Comparison to SBS

### E.1 1 Centimeter UHNA3 Scattered Power

### E.2 100 Micrometers CS2 Scattered Power

## Appendix F Measurement Theory

### F.1 Heterodyne Detection

### F.2 Lock-in Detection

## Appendix G Sensitivity

### G.1 Sensitivity Measurements

### G.2 Current Sensitivity Limitors

### G.3 Ultimate Sensitivity Limitor: Shot Noise

## Appendix H Alternative Configurations

### H.1 Mirrored Design

### H.2 Radial Acoustic Modes

### H.3 Shear Acoustic Modes

### H.4 Coherent Anti-Stokes Raman Spectrometer
